

## → Git (Global Information Tracker)

1. What is Git and Features of Git,  
Explain Advantages and disadvantages of Git?  
Ans: Git is a version control system used for tracking changes in computer files. It is generally used for source code management in software development.

- \* It allows multiple developers to work together.
- \* It supports non-linear development through its thousands of parallel branches.

### ⇒ Features of Git:

- ① Tracks History
- ② Free and Open Source
- ③ Supports non-linear development
- ④ create Backups
- ⑤ Scalable
- ⑥ Supports collaboration
- ⑦ Branching is Easier
- ⑧ Distributed Development

⇒ Git workflow is divided into 3 States:

- ① working directory: Modify files in your working directory
- ② Staging area (index): Stage the files and add snapshots of them to your staging area.
- ③ Git directory (Repository): Perform a commit that stores snapshots permanently to your

## Git directory.

### ⇒ Advantages of Git :-

- 1) Open source and free : It comes under GPL open source license. freely available on Internet. we can obtain its source code & modify it to meet your needs
- 2) Security : Git names & identifies things in database using popular cryptographic hash algorithm known as secure hash function (SHA1).
- 3) Flexibility : Git is meant to be adaptable, allowing it to accommodate wide range of Non-linear processes.
- 4) Git works on all machines.
- 5) Small and Quick
- 6) Branching and Merging
- 7) Non-linear development
- 8) Acceptance is widespread

### ⇒ Disadvantages:

- 1) Binary Files : Git does not excel at dealing with Binary Files.
- 2) Learning curve
- 3) Working in the wrong dev
- 4) Forced Collaboration
- 5) Permission for users

② Write git commands and write down the steps for how to push a files to github?

Ans: Git commands : working with local Repositories

- > git init : command git init is used to create empty git repository.
- \* Once the repository is initialized, process of creating other file begins.
- 1) git add : Add command used for checking status of files, to add those files to the staging area.
- 2) git commit : commit command makes sure that changes are saved to local repository.
- 3) git status : It tells the current state of repository.
- 4) git config : it is used initially to configure username & email.
- 5) git branch : it is used to determine what branch the local repository is on.
- 6) git merge
- 7) git checkout
- 8) git remote
- 9) git clone
- 10) git pull : It is used to fetch and merge changes from the remote repository to the

12) local repository  
git push: it is used to transfer commits or pushing content from local repository to remote repository.

`git push -u origin master`

⇒ using command line to push to

Step 1: Create a new repository

Fill up required details, i.e., repository name, description and also make repository public.

Step 2: open Git Bash

Step 3: create your local project in your desktop directed towards current working directory  
`cd 'path-name'`

Step 4: Initialize git repository  
`git init`

Step 5: Add the file to new local repository  
\* use `git add`. In your bash to add all files to the given folder  
\* use `git status` in your bash to view all files which are going to be staged to first commit.

Date \_\_\_\_\_  
Page \_\_\_\_\_

Step 6: commit files staged in your local repository by writing commit message  
`git commit -m "your message"`

Step 7: copy your remote repository's url from GitHub

Step 8: Add the url copied, which is your remote repository to where your local content from your repository is pushed.

`git remote add origin 'your-url-name'`

Step 9: Push the code to your local repository to GitHub

`git push -u origin master`

Step 10: View your files in your repository Hosted on GitHub.
